

Cascading Broadband Optical Splitters

Article Overview

Cascading broadband optical splitters use multiple stages of splitters in series to efficiently distribute optical signals in PON networks, reducing fiber counts and deployment costs while maintaining scalability.

Overview of Cascaded Splitters

Cascaded optical splitters, also known as distributed splitting, involve connecting multiple splitters in series between the Optical Line Terminal (OLT) and end-user Optical Network Terminals (ONTs) (OLT → Splitter 1 → Splitter 2 → ONT) rather than using a single high-ratio splitter. This approach allows service providers to achieve high overall split ratios (e.g., 1:32 or 1:64) while minimizing fiber usage and splicing requirements .

Advantages

- **Reduced Fiber Count:** By splitting closer to end-users, cascaded architectures lower the number of fibers needed from the OLT, saving duct space and reducing cable management complexity .
- **Cost-Effective Deployment:** Smaller fiber cables (24-48 fibers) and fewer splices reduce material and labor costs, accelerating network rollout .
- **Incremental Service Activation:** Customers can be connected progressively as construction continues, without waiting for the entire network to be completed .
- **Flexibility in Low-Density Areas:** Particularly suitable for rural or less populated regions, cascaded splitters optimize fiber usage and reduce infrastructure load
