

# Differential photoelectric encoder signal inversion

## Overview

The most straightforward method to invert a photoelectric sensor's output is through hardware. Many industrial sensors feature a DIP switch or a jumper on the enclosure, labeled as "L/D" (Light/Dark) or "NO/NC" (Normally Open/Normally Closed). By toggling this switch, you. A photoelectric signal, output by a photoelectric receiver, may detrimentally change after the photoelectric encoder is used for a period of time or when the environment changes; this will directly affect the accuracy of the encoder and lead to fatal errors in the encoder. As an electrical engineer, you must grasp how to configure these sensors to respond inversely to light conditions. Typically, a. The grating eddy-current of DGECE consists of a circular array of trapezoidal reflection conductors and 16 trapezoidal coils with a special structure to form a differential relationship, which are respectively located on the code plate and the readout plate designed by a printed circuit board. This is accomplished by a carrier recovery.
