

How to connect multiple access switches

Article Overview

You can connect multiple access switches using cascading, stacking, or clustering, depending on your network size, bandwidth needs, and switch compatibility.

Common Methods

1. Cascading: Cascading connects switches in series or in a tree/star topology, expanding the number of available ports. You can daisy-chain switches linearly (A-B-C) or in a ring for redundancy. Linear daisy chains are simple but lack redundancy, while ring topologies allow bi-directional data flow to maintain connectivity if one link fails. Cascading is flexible for mixing different switch models, and each switch maintains its own IP address, but it does not increase overall network bandwidth . 2. Stacking: Stacking combines multiple switches into a single logical unit, often requiring the same model. This method increases bandwidth and simplifies management, as the stack can be controlled as one switch. Stacking is ideal for high-performance networks where port density and throughput are critical, but it has a design-imposed limit on the number of switches that can be stacked . 3. Clustering: Clustering links switches to allow coordinated management while keeping them as separate devices. It provides some benefits of stacking without requiring identical models, but it may not boost bandwidth as effectively as stacking .

Topologies

- Star Topology: All access switches connect to a central core switch. This is scalable and simplifies traffic management.
- Tree/Bus Topology: Switches are connected hierarchically, often used in campus n...
