

How to determine the breakpoint on an optical power meter

Article Overview

The breakpoint on an optical power meter is identified by observing a significant drop in optical power readings, indicating a splice, connector, or fiber fault along the link.

Understanding the Breakpoint

A breakpoint in fiber optics refers to a location where the optical signal experiences a sudden loss, often due to a splice, connector, bend, or break. On an optical power meter, this is detected as a sharp decrease in measured power (dBm) compared to the expected link budget or reference reading.

Step-by-Step Procedure

- Prepare the Equipment
 - Clean the meter port, patch cords, and connectors to avoid contamination, which can falsely appear as a breakpoint (dirty connectors can add 1-5 dB of loss) .
 - Ensure the optical power meter is set to the correct wavelength matching the light source (e.g., 850 nm, 1310 nm, 1550 nm) .
- Establish a Reference
 - Connect a known good reference patch cord to the source and measure the baseline power. This reference reading represents the expected signal without losses .
- Connect the Fiber Under Test...
