

Why does fiber optic cable experience attenuation

Article Overview

Fiber optic cable attenuation occurs due to intrinsic material properties, scattering, absorption, and extrinsic factors like bending and connector losses, all of which reduce signal strength over distance.

Intrinsic Causes

Scattering is the primary intrinsic cause of attenuation in optical fibers. Microscopic density variations in the silica glass, formed during manufacturing, cause light to scatter in random directions, a phenomenon known as Rayleigh scattering. This effect is more pronounced at shorter wavelengths, which is why longer wavelengths like 1550 nm experience lower attenuation than shorter wavelengths like 850 nm . Absorption occurs when the glass material itself absorbs light energy and converts it into heat. This can happen at very short wavelengths, where photons excite electrons, or at longer wavelengths, where light interacts with molecular vibrations. Trace impurities, such as hydroxyl ions from water trapped in the glass, can create sharp absorption peaks, particularly near 1380 nm .

Extrinsic Causes

Bending losses happen when the fiber is bent too sharply. Macrobending refers to large, visible bends, while microbending involves tiny, microscopic bends caused by pressure from cable packaging or environmental stress. Both types allow light to escape from the core, increasing attenuation . Connector and splice losses occur at...
